(54) Title: DIRECTED HUMAN IMMUNE GLOBULIN FOR THE PREVENTION AND TREATMENT OF STAPHYLOCOCCAL INFECTIONS

(57) Abstract

This invention is directed to a Directed Human Immunoglobulin and compositions thereof for preventing or treating staphylococcal infections such as *S. epidermidis*.

1   <u>DIRECTED HUMAN IMMUNE GLOBULIN FOR THE PREVENTION</u>

2   <u>AND TREATMENT OF STAPHYLOCOCCAL INFECTIONS</u>

3   <u>I. GOVERNMENT INTEREST</u>

4   The invention described herein may be manufactured, licensed

5   and used by or for govermental purposes without the payment of any royalties

6   to us thereon.

7   <u>II. FIELD OF THE INVENTION</u>

8   This invention relates to Directed Human Immune Globulin for

9   the prevention and treatment of staphylococcal infections.

10   <u>III. BACKGROUND OF THE INVENTION</u>

11   Over the last two decades, staphylococci have become important

12   causes of infection in hospitalized patients. Because of their high prevalence

13   on the skin, staphylococci are ideally situated to cause serious infections in

14   debilitated or immunosuppressed patients. The staphylococcal species most

15   frequently pathogenic in humans are <u>Staphylococcus aureus</u> (SA) and

16   <u>Staphylococcus epidermidis</u> (SE). Both groups have developed resistance to

17   multiple antibiotics making antimicrobial therapy difficult. In recent years SE

18   has become a major cause of nosocomial infection in patients whose treatments

19   include the placement of foreign materials such as cerebrospinal fluid shunts,

-2-

1   vascular catheters or joint prostheses. SE is a common cause of post operative

2   wound infections peritonitis in patients with continuous ambulatory peritoneal

3   dialysis. Patients with impaired immunity (malignancy, bone marrow

4   transplant) or those receiving parenteral nutrition through central venous

5   catheter are also at high risk for developing SE sepsis (Patrick, J. Pediat.,

6   1990).

7   SE has emerged as a common cause of neonatal nosocomial

8   sepsis in premature infants. As shown by Fleer and colleagues, (Pediatr Infect

9   Dis, 1983) SE infections frequently occur in immature babies that have

10   received parenteral nutrition. Premature babies have impaired immunity with

11   deficiencies in antibodies, complement and neutrophil function. Lipid infusion

12   is now a standard ingredient of parenteral nutrition therapy in many nurseries

13   and may further impair immunity to bacterial infection as disclosed by Fischer

14   and colleagues (Lancet, 1980; 2:819-20). Recent studies have associated

15   coagulase negative staphylococcal bacteria in neonates with lipid emulsion

16   infusion (Freeman and colleagues, N. Engl. J. Med, 1990). Further studies by

17   Fleer and colleagues (J Inf Dis, 1985) showed that neonates had low levels of

18   opsonic antibody to SE despite the fact that the sera had clearly detectable

19   levels of IgG antibodies to SE peptidoglycan (opsonic antibodies for

20   staphylococcus have been considered to be directed to the peptidoglycan

21   antigens). While these studies suggested that neonatal susceptibility to SE

22   might be related to impaired oposonic activity, it is not clear if antibodies

-3-

1   directed against SE are opsonic or would be capable of providing protection

2   when given passively to neonates. Further, it is unknown whether the

3   presence of intralipid, which further impairs phagocytosis and killing of

4   bacteria by phagocytes, would inhibit the activity of antibody.

5   The opsonic activity of pooled human immunoglobulin for SE

6   was studied by Clark and colleagues (J Med Microbiol, 1986), and showed that

7   complement and IgG were both critical for efficient opsonization of SE. They

8   noted, however, that in some studies complement was not required and that

9   contrary to the report of Fleer (1985), absorption of serum with peptidoglycan

10   may remove the opsonic activity for SE. Further studies by Clark and Easmon

11   (1986) showed that several lots of standard intravenous immune globulin

12   (IVIG) had variable opsonic activity for SE. One third of the IVIG lots had

13   poor opsonization with complement and only 2 of 14 were opsonic without

14   complement. Despite the fact that the IVIG lots are made from large plasma

15   donor pools good opsonic antibody to SE was not uniformly present. Their

16   studies focused on potential use of immunoglobulin to boost peritoneal defenses

17   in patients receiving continuous ambulatory peritoneal dialysis and did not

18   examine whether IVIG could be utilized for the prevention or treatment of

19   bacterial sepsis, or the use of antibody to prevent or treat sepsis and lethal

20   infection in immature or immunosuppressed patients and Specifically, no in

21   vivo studies were done to test antibody to prevent or treat

-4-

1   SE. There is no evidence therefore that the antibody would provide beneficial

2   therapy in a setting of immaturity or impaired immunity.

3   The opsonic assays, that are currently used are slow and

4   cumbersome for screening blood, plasma or immune globulin for antibodies to

5   SE. It would be important to have a rapid antigen binding assay to screen for

6   SE antibody, if that assay further correlated with opsonic activity in vitro and

7   protection in vivo.

8   In order to determine if IgG is capable of enhancing protection

9   against SE, a suitable animal model that is comparable to patients with SE

10   infections is required. This is critical since neonates have low levels of

11   complement and impaired neutrophil and macrophage function. While opsonic

12   activity of immune globulin may be adequate under optimal conditions in vitro,

13   protection may not occur in patients with immature or impaired immune

14   systems. As has been demonstrated by Clark and colleagues (J Clin Pathol,

15   1986), most IVIG preparations were not opsonic when complement was

16   removed. However, since SE has low virulence, suitable animal models of SE

17   sepsis have not been available.

18   Yoshida and collegues, (J Microbiol, 1976) reported on a

19   virulent strain of SE that infected mature mice with 90 - 100% of mice dying

20   within 24 - 48 hours. This model is very different from that seen in patients

21   and may represent an unusual type of SE infection. When they analyzed 80

22   fresh isolates of SE from humans, they were not able to kill mice. Non-human

1   antibody to a new SE surface polysaccharide protected the mice from the

2   virulent SE strain. A later report by Yoshida and colleagues (J Med

3   Microbiol, 1977) confirmed their previous observations. Passive prophylaxis

4   with immunization induced non-human antibody showed that the IgG fraction

5   did not protect while the IgM fraction did provide protection. Thus

6   demonstrating in this model that IgG antibody was not protective. As noted

7   previously herein neonates had good levels of IgG to SE, but had low levels of

8   opsonic antibody (Fleer and colleagues, J. Infect. Dis, 1985), consistent with

9   the findings in this study and showing that the role of IgG in protection against

10   SE is unclear. In 1987 the report by Ichiman and colleagues (J Appl Bacteriol,

11   1987) extended their animal studies to include analysis of protective antibodies

12   in human serum against their selected virulent strains of SE. Protective

13   antibody was found in the IgA, IgM and IgG immunoglobulin fractions. These

14   studies are in conflict with their previous data showing that IgG was not

15   protective and fails to establish a definitive role for any of the immunoglobulin

16   classes (IgG, IgM or IgA).

17   In the animal model described by Yoshida, Ichiman and

18   colleagues mature, non-immunosuppressed mice were used and death was

19   considered to be related to toxins not sepsis (Yoshida and colleagues, J.

20   Microbiol, 1976). Most clinical isolates did not cause lethal infections in their

21   model. Since quantitative blood cultures were not done, it is not known

22   whether antibody would prevent or treat SE sepsis in immature

-6-

1   immunosupressed patients or specifically in the presence of intralipid.

2   Antibody provides protection in humans against certain

3   encapsulated bacteria such as Hemophilus influenzae and Streptococcus

4   pneumoniae. Individuals such as young infants who are deficient in antibody

5   are susceptible to infections with these bacteria and bacteremia and sepsis are

6   common. When antibody to these bacteria is present it provides protection by

7   promoting clearance of the bacteria from the blood. Immunoglobulin with

8   antibody to H. influenzae and S. pneumoniae protects infants from sepsis with

9   these bacteria. The article by Espersen and colleagues, (Arch Intern Med,

10   1987) discloses the use of an antigen binding RIA assay to analyze IgG

11   antibody to SE in patients with uncomplicated bacteremia and those with

12   bacteremia and endocarditis. This assay used an ultrasonic extract of SE to

13   identify SE specific IgG (the surface antigen in this study differs from the

14   antigen used by Yoshida and colleagues which was obtained by a different

15   method; gentle sonic oscillation). None of the patients with uncomplicated

16   bactermia had IgG antibodies to SE. These data would suggest that IgG is

17   unnecessary for effective eradication of SE from the blood. In addition, 89%

18   of bacteremic patients with endocarditis developed high levels of IgG to SE.

19   In these patients, IgG was not protective since high levels of IgG antibody

20   (which may have developed late) were associated with serious bacteremia and

21   endocarditis. Based on these studies the protective role of IgG in SE sepsis

22   and indocarditis is not established, especially in the presence of immaturity,

-7-

1   debilitation, intralipid infusion, or immunosuppresion. In addition, the

2   extensive review of Patrick et al. (J. Pediat., 1990) does not include

3   immunoglobulin as a potential prophylactic or therapeutic agent for SE

4   infections.

5   It has been recognized by the medical community that SE is an

6   important pathogen in certain high risk individuals, such as patients with

7   foreign body implants, premature neonates and immunosuppressed patients.

8   Accordingly there is a need for a human immune globulin that would prevent

9   or treat SE infections such as, sepsis or endocarditis and promote clearance of

10   SE from the blood of such high risk people.

11   IV. SUMMARY OF THE INVENTION

12   It is therefore an object of the present invention to provide a

13   novel Directed Human Immune Globulin for preventing or treating

14   staphylococcal infections. We have found that it is useful to screen serum

15   (plasma) or pooled immunoglobulin for specific antibody to S. epidermidis to

16   produce Directed Human Immune Globulin to this pathogen. This Directed

17   Human Immune Globulin is different from standard human immune globulin

18   preparations in that it has high levels of human anti-staphylococcal antibodies

19   that react with surface antigens of S. epidermidis and enhance phagocytosis

20   and killing of S. epidermidis in vitro, (opsonophagocytic bactericidal activity

21   greater than 80%). In addition, Directed Human Immune Globulin for S.

-8-

1   epidermidis enhances immunity in vivo and prevents lethal infection as well as

2   enhancing clearance of S. epidermidis from the blood in conditions of

3   immaturity and impaired immunity. This is surprising since

4   immunosuppression or immaturity would be expected to render the antibody

5   ineffective by impairing the ability of phagocytic cells to engulf and kill the S.

6   epidermidis.

7   It is also another advantageous object of the present invention

8   that while standard immunoglobulin pools or normal donors do not have

9   reliable levels of opsonic antibody for S. epidermidis, Directed Human

10   Immune Globulin when given intravenously immediately provides specific

11   antibodies to promote phagocytosis and killing of S. epidermidis by

12   phagocytes. A further advantages of the present invention is that by providing

13   opsonic antibody to immature or immunosuppressed patients infected with SE,

14   antibiotic therapy may be enhanced by improved S. epidermidis clearance from

15   the blood or site of infection. Another advantage is that since Directed Human

16   Immune Globulin given intravenously or intramuscularly can raise the level of

17   antibodies in the blood of patients, Directed Human Immune Globolin could

18   prevent S. epidermidis from causing bacteremia and local infections.

19   The method of producing the Directed Human Immune Globulin

20   for S. epidermidis involves:

21   a) screening plasma (pools of immunoglobulin or plasma;

22   immunoglobulin or immunoglobulin preparations) for antibodies to S.

1   epidermidis using an in vitro antigen-binding assay: (ELISA), followed by

2   confirmation of functional activity using an in vitro opsonophagocytic

3   bactericidal assay (bactericidal activity greater than 80%).

4   b) Protective efficacy can be documented in vivo by

5   analyzing protective activity of the Directed Human Immune Globulin using a

6   suckling rat model of neonatal S. epidermidis sepsis (mortality and bacterial

7   clearance). We believe that this is the first in vivo model to test antibody

8   effectiveness in the presence of immaturity and/or intralipid induced immune

9   suppression.

10   These methods could be repeated using other staphylococci such as SA

11   instead of SE to produce Directed Human Immune Globulin for S. aureus.

12   This novel Directed Human Immune Globulin for SE could be used to

13   prevent lethal SE infections in high risk patients such as neonates and adults in

14   intensive care units or patients with in-dwelling foreign bodies such as venous

15   and arterial catheters or ventricular shunts. Directed Human Immune Globulin

16   could also be used in addition to antibiotics as adjunctive therapy to enhance

17   bacterial clearance in patients treated for SE infections.

18   Other objects, features and advantages of the present invention will

19   become apparent from the following detailed description. It should be

20   understood, however, that the detailed description and specific examples, while

21   indicating preferred embodiments of the invention, are given by way of

22   illustration only, since various changes and modifications within the spirit and

-10-

1   scope of the invention will become apparent to those skilled in the art from

2   this detailed description.

3   The terms Standard Human Immunoglobulin and Directed

4   Human Immune Globulin for S. epidermidis as used in this application are

5   defined as follows: Standard Human Immunoglobulin - immune human

6   globulin that was prepared by pooling immunoglobulin from many donors,

7   without selecting donors or screening the immunoglobulin to ensure antibody

8   acitivity for S. Epidermidis.

9   Directed Human Immune Globulin for S. epidermidis - Immune

10   globulin prepared by screening for antibody to S. epidermidis (Bactericidal

11   Activity > 80%), thereby providing a human immune globulin with protective

12   levels of antibody to S. epidermidis and suitable for preventing or treating S.

13   epidermidis infections. Bactericidal Activity-The percentage of bacteria killed

14   with the addition of antibody, using a neutrophil mediated opsonophagocytic

15   bactericidal assay after 2 hours of incubation at 37°C.

16   V. BRIEF DESCRIPTION OF THE DRAWINGS

17   Figure 1

18   Figure 1 shows that when several pools of human standard intravenous

19   immunglobulin were analyzed, there was a marked difference in the antibody

20   activity to S. epidermidis as measured by an antigen binding assay (ELISA,

-11-

1   highest O.O. reading at 1 1/2 hrs using 1:100 Dil). These were large pools of

2   IgG, purified by several companies using various techniques. Of three pools

3   with the highest titers, two were from Cutter Laboratories, Berkeley

4   California, (40P07, 40R09) and one was from Sandoz, East Hanover, N.J.

5   (069). One preparation from Cutter also had next to the lowest activity

6   (2801). These data show that standard unscreened human immunoglobulin has

7   variable levels of antibody to S. epidermidis and that no single method used to

8   prepare the immunoglobulin or utilizing a large donor pool size will ensure

9   good antibody activity to S. epidermidis. In addition, a donor was shown to

10   have high antibody activity (Sam) to S. epidermidis demonstrating the

11   feasibility of identifying units of plasma or, plasma donors with high levels of

12   antibodies to staphylococcus.

13   Figure 2

14   Figure 2 shows that using an in vitro functional (opsonic) assay that

15   measures the ability of immunoglobulin to promote phagocytosis and killing of

16   S. epidermidis by neutrophils in the presence of complement, that opsonic

17   activity is also variable in various lots and preparations of standard human

18   immunoglobulin. The figure also shows that the immunoglobulins identified

19   by ELISA as having high levels of antibody to S. epidermidis also had high

20   levels of functional antibody in vitro. This is critical since this study shows

21   that IgG that binds to TCA extracted S. epidermidis antigen will promote

-12-

1   phagocytosis and killing of S. epidermidis. Therefore, using in vitro screening

2   assays, one could select a Directed Human Immune Globulin for S.

3   epidermidis that would have reliable levels of antibody to prevent or treat S.

4   epidermidis infections.

5   It also shows that unscreened immune globulin would not

6   provide reliable protection, since many standard human immunoglobulin lots

7   have little or no opsonic activity for S. epidermidis. Hence, standard human

8   immune globulin would not ensure uniformly high levels of antibody to SE and

9   would not be uniformly protective despite the fact that large numbers of donors

10   might be expected to provide good levels of antibody to a common bacteria

11   such as S. epidermidis.

12   Figure 3

13   Figure 3 shows that Directed Immune Globulin protects animals from

14   developing prolonged S. epidermidis bacteremia while standard immune

15   globulin did not. Animals treated with Directed Immune Globulin had lower

16   peak bacteremia levels (9.2×10^2 vs. 6.5×10^3) and cleared the bacteremia

17   more efficiently (at 72 hours, 5 bact. per ml vs. 380 bact. per ml; geometric

18   mean level). In addition 72 hours after infection, 18/24 (75%) animals given

19   Directed Immune Globulin had cleared their bacteremia and 100% survived,

20   while only 4/20 (20%) animals given standard immune globulin died and only

21   1/16 (6%) cleared their bacteremia during that 72 hour period. In addition to

-13-

1　prevention, since Directed Immune Globulin enhanced S. epidermidis

2　clearance, it would be a valuable adjunct to antibiotic therapy for people

3　infected with S. epidermidis, since many of these patients have imparied

4　immunity and may not clear the bacteria efficiently.

5　## VI. DETAILED DESCRIPTION OF PREFFERED EMBODIMENTS

6　### EXAMPLES

7　The herein offered examples provide methods for illustrating, without any

8　implied limitation, the practice of this invention in the production of Directed

9　Human Immune Globulin for Staphylococcus epidermidis and the use of said

10　Immune Globulin for the prevention or treatment of infections caused by

11　Staphylococcus epidermidis.

12　The profile of the representative experiments have been chosen

13　to illustrate methods for producing Directed Human Immune Globulin to S.

14　epidermidis and to demonstrate its usefulness to prevent or treat S. epidermidis

15　infections.

16　### Materials and Methods

17　Staphylococcal Strains: Although any S. epidermidis strains

18　could be used, in these experiments we used two strains from the American

-14-

1   Type Culture Collection, Rockville, MD (ATCC #31432 and ATCC #35984).

2   A clinical isolate (Hay) from the blood of a child with S. epidermidis sepsis

3   was also used and is also on deposit at the American Type Culture Collection.

4   Materials and Methods

5   Immunoglobulin: Standard Intravenous Immunoglobulin was

6   used in these experiments to represent large immunoglobulin pools.

7   Preparations from several companies were analyzed for comparison, to include

8   Gamimmune, Cutter Laboratories Inc. Berkeley, California; Sandoglobulin,

9   Sandoz, East Hanover, N.J.; Gammagard, Hyland, Los Angeles, California.

10   Serum from individual donors were also analyzed for antibody activity to S.

11   epidermidis.

12   Trichloroacetic Acid (TCA) Antigen Extraction

13   Staphylococcus epidermidis strains (ATCC #35984, ATCC

14   #31432 and Hay) were grown to log phase at 37°C in 1000 ml of Tryptic Soy

15   Broth (Difco). The bacteria were then centrifuged at 2500 RPM for 10

16   minutes and the supernatant was aspirated and discarded. The bacterial button

17   was resuspended in 200 ml of 2% trichloroacetic acid (TCA) and stirred

18   overnight at 4°C. The mixture was then centrifuged at 2500 RPM for 10

19   minutes and the supernatant aspirated. To the supernatant, 4 volumes of

20   absolute ethanol were added and refrigerated overnight at 4°C. After

21   centrifugation at 2500 RPM for 10 minutes, the supernatant was removed and

-15-

1   discarded. Then, five milliliters of normal saline was added to the antigen

2   precipitate, it was cultured to ensure sterility and then lyophilized for storage.

3   Antigen Binding Studies Using Enzyme-Linked

4   Immunoabsorbent Assay (ELISA)

5   S. epidermidis Antigen was dissolved in carbonate buffer at a

6   concentration of 25 micrograms/ml. To each well of A 96-well flat-bottomed

7   microtiter plate (NUNC, Roskilide, Denmark) 100 microliters were added and

8   stored at 4°C until used. Immunoglobulin was diluted to 1% and 2-fold

9   dilutions prepared in phosphate-buffered saline-Tween . To each well was

10   added 100 microliters of the serial dilutions and the plates were incubated for 1

11   hour at 4°C. The plates were washed four times with H_2O-Tween . Alkaline

12   phosphatase linked goat anti-Human IgG (100 microliters;1:250) was added,

13   the plates were incubated for 1 hour at 4°C and then washed H_2O-Tween and

14   100 microliters of P-nitrophenyl phosphate substrate in diethanolamine buffer

15   were added. After 90 minutes of incubation at room temperature, the color

16   development was determined by absorbance at 405 nm.

17   Opsonic Assay:

18   To determine the functional antibody to S. epidermidis in the

19   immune globulin pools and sera, a neutrophil mediated bactericidal assay was

-16-

1 used. Neutrophils were isolated from adult venous blood by dextran

2 sedimentation and ficall-hypaque density centrifugation. Utilizing a microtiter

3 plate assay that requires a total volume of 0.1 ml/well, washed neutrophils

4 (approximately 10^6 cells) were added to round-bottomed microtiter wells along

5 with 3×10^4 approximately mid-log phase bacteria. Newborn rabbit serum (10

6 microliters; screened to assure absence of antibody to S. epidermidis) was

7 used as a source of active complement. Forty microliters of 5% standard

8 immune globulin (or serum) was added and the microtiter plates were

9 incubated at 37°C with constant, vigorous shaking. Samples (10 microliters)

10 were taken from each well at zero time and after 2 hours of incubation,

11 diluted, vigorously vortexed to disperse the bacteria and cultured on blood agar

12 plates overnight at 37°C to quantitate the number of viable bacteria. Controls

13 consisted of neutrophils alone, complement alone and neutrophils plus

14 complement.

15 Staphylococcal Sepsis Model:

16 A suckling rat model was used to determine the in vivo activity

17 of antibody to S. epidermidis. Wistar rats (2 days old) were given 0.2 ml of

18 20% Intralipid (Cutter, Berkeley California,) intraperitoneally at 0800 and

19 1400. At three days of age each animal was again given, 0.2 ml of 20%

20 intralipid at 0800 and 1400 and 0.2 ml of 5% immunoglobulin or serum was

21 given IP. Shortly after the last dose of intralipid, 0.05ml (approx. 5×10^7)

-17-

1   mid log phase S. epidermidis were injected subcutaneously just cephalad to the

2   tail. Suckling rats less than 24 hours old also develop lethal S. epidermidis

3   sepsis when infected with 10^7-10^8 S. epidermidis subcutaneously. To analyze

4   bacteremia levels in selected animals, 0.01 ml of blood was obtained from the

5   tails of the suckling rats, 24, 48, and 72 hours after infection. The blood was

6   collected under sterile conditions in micropipettes and serially diluted in

7   Tryptic Soy Broth (Difco). Bacteria were subcultured onto plates to ensure S.

8   epidermidis bacteremia and all animals were followed five days to determine

9   survival.

10   Results

11   Antigen Binding Activity of Human Immunoglobulin for S.

12   epidermidis.

13   The results of the ELISA testing of several standard

14   immunoglobulin preparations for antibody to S. epidermidis are presented in

15   Figure 1. Most standard immune globulins contained low levels of antibody to

16   S. epidermidis. However, by screening for antibody to TCA extracted antigens

17   of S. epidermidis, some immunoglobulin lots and serum from one volunteer

18   donor were found to have increased levels of antibody to S. epidermidis (O.D.

19   readings 1.014, 1.026, and 1.002). Variations in antibody to S. epidermidis

20   occurred between preparations prepared by different techniques and lot to lot

21   variation in a single preparation was seen as well, indicating that all

22   immunoglobulin pools were not the same.

-18-

1   <u>Opsonic Activity of Human Immunoglobulins for S. epidermidis</u>.

2   All antibody directed against a given organism may not enhance

3   immunity and provide enhanced protection from infection. Stated differently,

4   antibodies can bind to bacteria and yet not enhance opsonization <u>in vitro</u> or

5   clearance from the blood of an infected host. Therefore a functional assay was

6   also utilized to determine if the antibody to <u>S. epidermidis</u> detected by ELISA

7   was also capable of promoting phagocytosis and killing of the organism by

8   neutrophils (Figure 2). Opsonic antibody activity ranged from low (<25%

9   bactericidal activity), to moderate activity (25-80%) and a few had high

10   bactericidal activity (>80%). Therefore two standard human immune globulin

11   preparations with high bactericidal activity were selected as Directed Human

12   Immune Globulin for <u>S. epidermidis</u> based on <u>in vitro</u> assays that measured

13   antibody binding to TCA <u>S. epidermidis</u> antigens and opsonic antibody activity

14   determined by <u>in vitro</u> testing. Serum from a single donor also had good

15   opsonic activity for <u>S. epidermidis</u> (>80% opsonophagocytic bactericidal

16   activity). While serum and plasma from several individuals have been studied

17   only this donor had high opsonic activity. Therefore donor screening could

18   detect individual blood or plasma donors that could contribute immunoglobulin

19   that could be pooled as an alternate method to produce a

-19-

1   Directed Human Immune Globulin for S. epidermidis. In addition blood or

2   plasma units could be screened for pooling as well.

3   Animal Protection Studies

4   Discription of Tables

5   Table 1

6   Table 1 shows the effect of Directed Human Immunoglobulin for

7   S. epidermidis (40R09) (which was selected by ELISA and opsonic assay

8   screening) compared to standard human immunoglobulin (that had moderate

9   activity for S. epidermidis) and saline control. Table 1 shows that untreated

10   control animals had about a 50% mortality while animals given Directed

11   Immune Globulin for S. epidermidis were fully protected (NO mortality).

12   Standard immune globulin gave only partial protection. Other standard

13   immune globulin lots with lower levels of antibody to S. epidermidis would be

14   even less effective, since mortality was much higher with saline. However,

15   one would not expect that Directed Immune Globulin would be always 100%

16   effective, but that it would consistently improve survival over standard immune

17   globulin or untreated animals.

18   Table 2

19   Table 2 demonstrates that Directed Immune Globulin produced

20   in rabbits by immunization (S. epidermidis vaccine) produced survival similar

-20-

1   to Directed Human Immune Globulin produced by screening immunoglobulin

2   for antibody to S. epidermidis. Immunization of individuals with S.

3   epidermidis vaccine and collecting plasma for immunoglobulin extraction

4   would be another method for producing Directed Human Immune Globulin for

5   preventing or treating S. epidermidis infections.

6   Table 3

7   Table 3 shows that intralipid causes a dose related increased

8   mortality in suckling rats infected with S. epidermidis. Control animals

9   receiving Intralipid alone had 100% survival (43/43) while immature rats given

10   16 gm/kg of Intralipid had only 46% survival (6/13). The high dose of

11   Intralipid appears to impair the immune system sufficiently to allow the

12   normally avirulent S. epidermidis to overwhelm the baby animals.

13   Table 4

14   Table 4 shows that normal 3 day old suckling rats not given

15   Intralipid, but infected with S. epidermidis develop bacteremia. However,

16   over 72 hrs their immune system is able to clear the organisms from the blood

17   and all of the baby rats survive.

-21-

1   Table 1 shows the Directed Human Immune Globulin for S.

2   epidermidis (selected by screening standard immunoglobulin for opsonic or

3   antigen binding activity for S. epidermidis) provides complete protection from

4   lethal infection in the setting of impaired immunity with Intralipid while

5   standard immune globulin (with moderate antibody levels) had only partial

6   protection (1 out of 5 aminals died compared to about 50% with saline).

7   Additional studies with another immunoglobulin preparation, (Alpha

8   Pharmaceuticals; Directed Human Immune Globulin 8016A >90% opsonic

9   activity, versus standard human immune globulin, 8007A < 50% opsonic

10   activity) showed that the Directed Human Immune globulin also provided

11   enhanced survival (8016A-64/95 (67%) vs. 8007A-39/90 (43%)) over standard

12   human immune globulin. Even more striking was the fact that the Directed

13   Human Immune Globulin decreased the peak level of S. epidermidis

14   bacteremia and promoted rapid clearance of the bacteria (Figure 3). These

15   studies showed that antibody was important for protection against S.

16   epidermidis enhanced bacterial clearance from the blood and could be an

17   effective prophylactic or therapeutic modality even in the immature host with

18   impaired immunity. Many of the animals treated with standard human immune

19   globulin remained bacteremic 72 hours after infection while only 1/20 animals

20   was still bacteremic at 72 hours after receiving the Directed Human Immune

21   Globulin. In addition the mean bacteremia level at 72 hours was

-22-

1   markedly different (bacteremia with Directed Human Immune Globulin 0.5 x

2   10^1 vs. bacteremia with standard human immune globulin 3.8 x10^2).

3   In further studies, rabbit Directed Immune Globulin for S.

4   epidermidis was produced by immunizing rabbits with S. epidermidis vaccine.

5   The vaccine induced Directed Immune Globulin was compared with Directed

6   Human Immune Globulin produced by screening immunoglobulin for antibody

7   to S. epidermidis (Table 2). Vaccine induced Directed Immune Globulin had

8   similar protective activity to Directed Human Immune Globulin produced by

9   screening (9/11 vs. 12/13 survived) and each was better than controls (11/19

10   survived). These data show that S. epidermidis vaccine induced antibody

11   could be used for prevention and treatment of S. epidermidis infections and

12   that vaccine could be used to produce a Directed Human Immune Globulin.

13   TABLE 3

14   Many bacteria such as S. epidermidis are not pathogenic in

15   normal people. However, in babies with an immature immune system or

16   impaired immunity as is seen with intralipid, S. epidermidis may cause sepsis

17   and death. It is critical therefore, that any animal model to test antibody

18   effectiveness should include these factors. To our knowledge this is the first

19   time that antibody to Staphylococcus epidermis has been shown to provide

20   protection and enhance bacterial clearance in an immature and/or

-23-

1   immunosuppressed host. Intralipid given in dosage up to 16 gm/kg did not

2   cause death in any baby animals (controls, table 3). In the absence of

3   Intralipid, the 3 day old animals will become bacteremic with S. epidermidis

4   after infection, but will clear the infection over 72 hours and survive (Table 4).

5   However, Intralipid did impair immunity in a dose related fashion and when

6   the 3 day old animals were infected with S. epidermidis lethal sepsis occurred

7   in up to 67% of the animals. Baby rats in the first day of life also do not clear

8   bacteriemia well (due to immature immunity) and develop lethal sepsis. In

9   these models baby rats were unable to clear the S. epidermidis bacteremia and

10   developed lethal sepsis. Directed Human Immune Globulin was able to

11   enhance survival and promote bacterial clearance while standard human

12   immune globulin did not enhance clearance (Fig 3).

13   TABLE 4

14   When SE is injected into normal baby rats, they become

15   bacteremic in 2 hours and then begin to slowly clear the bacteria from the

16   blood. All of the animals cleared the bacteremia 72 hours after the infection.

17   thus suggesting that under normal circumstances neonatal immunity while

18   impaired can eventually control SE. However, studies in rats infectedd with S.

19   epidermidis shortly after birth have demonstrated that they can also develop a

20   lethal infection.

-28-

1   We claim:

2   1. A Directed Human Immune Globulin for the prevention or

3   treatment of Staphylococcus epidermidis infections.

4   2. A Directed Human Immune Globulin of Claim 1 which

5   contains a measured level of anti-staphylococcal IgG antibodies that react with

6   surface antigens of Staphylococcus epidermidis and promote phagocytosis and

7   killing of Staphylococcus epidermidis in vitro and/or protection against

8   Staphylococcus epidermidis in vivo.

9   3. The Directed Human Immune Globulin of Claim 2 wherein

10   the measured level of anti-staphylococcal IgG antibodies has an opsonic

11   activity within the range of about 80 to about 100 percent.

12   4. A pharmaceutical composition comprising an amount of

13   Directed Human Immune Globulin of Claim 1 sufficient to prevent or treat

14   infections by S. epidermidil and a pharmaceutically acceptable carrier therefor.

15   5. A pharmaceutical composition comprising a Directed Human

16   Immune Globulin of Claim 2.

-29-

1   6. A pharmaceutical composition comprising a Directed Human

2   Immune Globulin of Claim 3.

3   7. A method of preparing a Directed Human Immune Globulin

4   of Claim 1 by screening serum, plasma, or an immunoglobulin pool by S.

5   epidermidis ELISA or Opsonic Assays.

6   8. The method of Claim 7 wherein serum is screened by S.

7   epidermidis ELISA or Opsonic Assays.

8   9. The method of Claim 8 wherein the serum is screened by S.

9   epidermidis ELISA.

10   10. The method of Claim 8 wherein the serum is screened by

11   S. epidermidis Opsonic Assays.

12   11. The method of Claim 7 wherein the plasma is screened by

13   S. epidermidis ELISA or Opsonic Assays.

14   12. The method of Claim 11 wherein the plasma is screened by

15   S. epidermidis ELISA.

-30-

1   13. The method of Claim 11 wherein the plasma is screened by

2   S. epidermidis Opsonic Assays.

3   14. The method of Claim 7 wherein the immunoglobulin pool is

4   screened by S. epidermidis ELISA or Opsonic Assays.

5   15. The method of Claim 14 wherein the immunoglobulin pool

6   is screened by S. epidermidis ELISA.

7   16. The method of Claim 14 wherein the immunoglobulin pool

8   is screened by S. epidermidis Opsonic Assays.

9   17. A method of preparing a Directed Human Immune Globulin

10 of Claim 1 comprising the steps of: (a) immunizing plasma donors and (b)

11 removing plasma from said donors for Directed Immune Globulin preparation.

12   18. A method of assessing the protective level of Direct

13 Human Immune Globulin by using an immature or intralipid induced lethal

14 model to provide minimum protective standard comprising the steps of: (a)

15 screening with in vitro assays and (b) using animal lethality tests to ensure that

16 the immunoglobulin preparation provided protective antibody to S.

17 epidermidis.

-31-

1   19. A method of treating a host with a therapeutically- effective

2   amount of S. epidermidis of Directed Human Immune Globulin of Claim 1 by

3   intraveneous administration thereof.

4   20. A method of treating a host with a therapeutically effective

5   amount of S. epidermidis of Directed Human Immune Globulin of Claim 1 by
6   intramuscular administration thereof.

7   21. The method of Claim 19 wherein the host is treated prior to

8   infection with S. epidermidis.

9   22. The method of Claim 20 wherein the host is treated after

10   infection with S. epidermidis.

BOX II. OBSERVATIONS WHERE UNITY OF INVENTION WAS LACKING
This ISA found multiple inventions as follows:

I.   Claims 1-6 and 19-22, drawn to an immune globulin, a composition; a method of preparing an immune globulin and
a method of using the immune globulin, Classes 530, 435 and 424, Subclasses 389.5, 7.92 and 87, respectively.
II. Claim 17, drawn to a method of preparing an immune globulin, Class 424, Subclass 92.
III. Claim 18, drawn to a method of assessing the protective level of an immune globulin, Class 424, Subclass 9.
        The inventions are distinct, each from the othr because of the following reasons:
        Inventions II and I are related as process of making and product made. In the instant case the product as
claimed can be made by materially different processes such as the two different processes in Groups I and II.
        Further, the inventions as grouped are distinct, each from the other, because they represent different
inventive endeavors. The inventions of Groups I-II would not suggest the invention of Group III.
